Abstract. We show that the open unit ball of the space of operators from a finite dimensional Hilbert space into a separable Hilbert space (we call it “operator ball”) has a restricted form of normal structure if we endow it with a hyperbolic metric (which is an analogue of
the standard hyperbolic metric on the unit disc in the complex plane). We use this result to get a fixed point theorem for groups of biholomorphic automorphisms of the operator ball. The fixed point theorem is used to show that a bounded representation in a separable Hilbert space which has an invariant indefinite quadratic form with finitely many negative squares is unitarizable (equivalent to a unitary representation). We apply this result to find dual pairs of invariant subspaces in Pontryagin spaces. In the appendix we present results of Itai Shafrir about hyperbolic metrics on the operator ball.

Keywords. Hilbert space, bounded representation, unitary representation, hyperbolic space, fixed point, normal structure, biholomorphic transformation, indefinite quadratic form

1 Introduction

Let $K, H$ be Hilbert spaces; by $L(K, H)$ we denote the Banach space of all linear bounded operators from $K$ to $H$. We will denote the open unit ball of $L(K, H)$ by $B$ and call it operator ball. We say that a subset $M$ of $B$ is separated from the boundary if it is contained in a ball $rB$, for some $r \in [0, 1)$.

A group $G$ of transformations of $B$ will be called elliptic if all its orbits are separated from the boundary (this terminology goes back to [9]).

We call $G$ equicontinuous if, for each $\varepsilon > 0$ there is $\delta > 0$ such that if $A, B \in B$ and $\|A - B\| < \delta$ then $\|g(A) - g(B)\| < \varepsilon$ for all $g \in G$. This condition can be also called global equicontinuity because it is possible also to consider equicontinuity in a point.

Since $B$ is a bounded open set of a Banach space, one may consider holomorphic maps from $B$ to Banach spaces. We will deal with invertible holomorphic maps from $B$ onto $B$; such maps are called biholomorphic automorphisms of $B$. Our aim is to prove that if one of the spaces $K, H$ is finite-dimensional and the other is separable, then any elliptic group of biholomorphic automorphisms of $B$ has a common fixed point. More precisely we will prove the following result.

Theorem 1.1. Let $\dim K < \infty$ and $H$ be separable. For a group $G$ of biholomorphic automorphisms of $B$, the following statements are equivalent:

(i) $G$ is elliptic on $B$;
(ii) at least one orbit of $G$ is separated from the boundary;
(iii) $G$ is equicontinuous;
(iv) $G$ has a common fixed point in $B$.

Remark 1.2. The assumption $\dim K < \infty$ is essential, some of the results of this paper are known to fail without it, see, for example, the last paragraph of Section 8. As for separability of $H$, it is just a technical convenience, our approach works for non-separable $H$ also, with a bit more complicated proofs.
The result will be applied to the orthogonalization (or similarity) problem for bounded group representations on Hilbert spaces. This problem can be formulated as follows. Let $\pi$ be a representation of a group $G$ on a Hilbert space $H$. Under which conditions there is an invertible operator $V$ such that the representation $\sigma$ of $G$, defined by the formula $\sigma(g) = V \pi(g) V^{-1}$, is unitary?

Clearly a necessary condition is the boundedness of $\pi$: $\sup_{g \in G} \|\pi(g)\| < \infty$. In general it is not sufficient. Some sufficient conditions (on $G$ or $\pi$) are known, see the book [12]. We will show that a bounded representation $\pi$ of a group $G$ on a Hilbert space $H$ is similar to a unitary representation if it preserves a quadratic form $\eta$ with finite number of negative squares. The last condition means that $\eta(x) = \|Px\|^2 - \|Qx\|^2$ and $P, Q$ are orthogonal projections in $H$ with $P + Q = 1$ and $\dim(QH) < \infty$.

As a consequence we obtain that each bounded group of $J$-unitary operators on a Pontryagin space $\Pi_k$ has an invariant dual pair of subspaces. In other words the space can be decomposed into $J$-orthogonal direct sum $H_+ + H_-$ of positive and negative subspaces which are invariant for all operators in the group.

The proof of Theorem 1.1 is based on the analysis of the structure of the operator ball as a metric space with respect to the Carathéodory distance (see Chapters 4 and 5 of [6]). It was proved by Shafrir [15] that $B$ is a hyperbolic space with respect to this distance. Since [15] is not easily accessible, we present a proof of this result in an appendix to our paper, with the kind permission of the author. We will show that $B$ has a restricted form of a normal structure if $\dim(K) < \infty$.

In the case where $K$ is one-dimensional Theorem 1.1 was obtained in [17]; a transparent proof can be found in [10, Section 23].

2 Hyperbolic spaces

In our definition of hyperbolic spaces we follow fixed point theory literature (see e.g. [13], [14]). In geometric literature (see e.g. [3]) hyperbolic spaces are defined differently.

By a line in a metric space $(X, \rho)$ we mean a subset of $X$ which is isometric to the real line $\mathbb{R}$ with its usual metric (in the literature lines are also called metric lines or geodesic lines).

Let $(X, \rho)$ be a metric space with a distinguished set $M$ of lines. We say that $X$ is a hyperbolic space if the following conditions are satisfied:

(1) (Uniqueness of a distinguished line through a given pair of points) For each $x, y \in X$, there is exactly one line $\ell \in M$ containing both $x$ and $y$.

(2) (Convexity of the metric) To state the condition (see (2.3)) we need to introduce some more definitions and notation. The segment $[x, y]$ is defined as the part of the line $\ell \in M$ containing both $x$ and $y$, consisting of all $z \in \ell$ satisfying

$$\rho(x, y) = \rho(x, z) + \rho(z, y).$$

(2.1)
We write
\[ z = (1 - t)x \oplus ty \] (2.2)
if \( z \in [x, y] \), \( \rho(z, x) = t\rho(x, y) \), and \( \rho(z, y) = (1 - t)\rho(x, y) \) (where \( t \in [0, 1] \)).

The convexity condition is:
\[ \rho \left( \frac{1}{2}x \oplus \frac{1}{2}y, \frac{1}{2}x \oplus \frac{1}{2}z \right) \leq \frac{1}{2}\rho(y, z). \] (2.3)

Hyperbolic spaces satisfy also the following stronger form of the condition (2.3):
\[ \rho((1 - t)x \oplus ty, (1 - t)w \oplus tz) \leq (1 - t)\rho(x, w) + t\rho(y, z). \] (2.4)

(To get (2.4) from (2.3) we observe that, if for some value of \( t \) we have the inequalities \( \rho((1 - t)x \oplus ty, (1 - t)x \oplus tz) \leq t\rho(y, z) \) and \( \rho((1 - t)x \oplus tz, (1 - t)w \oplus tz) \leq (1 - t)\rho(x, w) \), then, by the triangle inequality, we have (2.4) for that value of \( t \). Using this observation repeatedly we prove the inequalities from this paragraph for \( t \) of the form \( \frac{k}{2^n} \) \((k \in \mathbb{N}, 1 \leq k \leq 2^n)\). Then we use continuity.)

A subset \( C \subset X \) is called **convex** if \( x, y \in C \) implies \([x, y] \subset C \). Sometimes we say \( \rho\)-**convex** instead of convex, to avoid confusion with other natural notions of convexity for the same set. We use the notation \( E_{a,r} \) for \( \{ x \in X : \rho(a, x) \leq r \} \) and call such sets **closed balls**. The condition (2.4) implies that in a hyperbolic space all closed balls are convex.

### 3 Normal structure

Let \( M \) be a subset in a metric space \((X, \rho)\). The **diameter** of \( M \) is defined by
\[ \text{diam}M = \sup \{ \rho(x, y) : x, y \in M \} \] (3.1)

A point \( a \in M \) is called **diametral** if
\[ \sup \{ \rho(a, x) : x \in M \} = \text{diam}M. \]

A hyperbolic space \( X \) is said to have **normal structure** if every convex bounded subset of \( X \) with more than one element has a non-diametral point.

This notion goes back to Brodskii and Milman [4] who proved that uniformly convex Banach spaces (which are hyperbolic spaces) have normal structure. Takahashi [18] introduced and studied normal structure in somewhat more general context. See [2, Chapter 3] for a nice account on those aspects of fixed point theory which are related to the geometry of Banach spaces.

**Lemma 3.1.** Let \( M \) be a separable bounded convex subset of a hyperbolic space \( X \) and \( \alpha \) be the diameter of \( M \). If all points of \( M \) are diametral then \( M \) contains a sequence \( \{a_n\} \) with the property: \( \lim_{n \to \infty} \rho(a_n, x) = \alpha \) for each \( x \in M \).
Proof. Let \( \{c_n\} \) be a dense sequence in \( M \). We define a sequence \( \{b_n\} \) of “centers of mass” by the following rule: \( b_1 = c_1, \ b_{n+1} = \frac{n}{n+1}b_n + \frac{1}{n+1}c_{n+1} \). By convexity of \( \rho \) we have

\[
\rho(x, b_n) \leq \frac{1}{n} \sum_{k=1}^{n} \rho(x, c_k)
\]

for all \( n \in \mathbb{N} \). Indeed for \( n = 1 \) this is obvious. If it is true for some \( n \), then

\[
\rho(x, b_{n+1}) \leq \frac{1}{n+1} \rho(x, c_{n+1}) + \frac{n}{n+1} \rho(x, b_n) \leq \frac{1}{n+1} \rho(x, c_{n+1}) + \frac{n}{n+1} \frac{1}{n} \sum_{k=1}^{n} \rho(x, c_k) = \frac{1}{n+1} \sum_{k=1}^{n+1} \rho(x, c_k).
\]

By convexity of \( M \) we have \( b_n \in M \) for each \( n \in \mathbb{N} \). Our assumption implies that \( b_n \) is diametral, hence there is a point \( a_n \in M \) with \( \rho(b_n, a_n) \geq (1 - \frac{1}{n^2})\alpha \). It follows that

\[
(1 - \frac{1}{n^2})\alpha \leq \frac{1}{n} \sum_{k=1}^{n} \rho(a_n, c_k).
\]

If \( \rho(a_n, c_j) < (1 - \frac{1}{n})\alpha \), for some \( j \leq n \), then \( \frac{1}{n} \sum_{k=1}^{n} \rho(a_n, c_k) < \frac{1}{n}(1 - \frac{1}{n^2})\alpha + \frac{n-1}{n} \alpha = (1 - \frac{1}{n^2})\alpha \), a contradiction. Hence \( \rho(a_n, c_j) \geq (1 - \frac{1}{n})\alpha \) for \( j \leq n \). This shows that \( \lim_{n \to \infty} \rho(a_n, c_j) = \alpha \) for each fixed \( j \). Since the sequence \( \{c_j\} \) is dense in \( M \), the lemma is proved. \( \square \)

4 The invariant distance in the operator ball

Recall that \( K, H \) denote Hilbert spaces and \( B \) is the open unit ball of \( L(K, H) \). For \( A, X \in B \) set

\[
M_A(X) = (1 - AA^*)^{-1/2}(A + X)(1 + A^*X)^{-1}(1 - A^*A)^{1/2}.
\]

(4.1)

Clearly all \( M_A \) are holomorphic on \( B \). They are called the Möbius transformations. It can be proved that \( M_A^{-1} = M_{-A} \) (see [8], Theorem 2). Hence each Möbius transformation is a biholomorphic automorphism of \( B \). Since \( M_A(0) = A \) the group of all biholomorphic automorphisms is transitive on \( B \).

We set

\[
\rho(A, B) = \tanh^{-1}(||M_{-A}(B)||).
\]

(4.2)

It is easy to see that \( \rho \) coincides with the Carathéodory distance \( c_B \) in \( B \). Indeed, by [6, Theorem 4.1.8], \( c_B(0, B) = \tanh^{-1}(||B||) \) (this holds for the unit ball of every Banach space). Since \( c_B \) is invariant and \( M_A \) sends \( A \) to \( 0 \) we get:

\[
c_B(A, B) = \tanh^{-1} ||M_{-A}(B)|| = \rho(A, B).
\]

(4.3)

Hence \( \rho \) is invariant with respect to biholomorphic automorphisms. I. Shafir [15] proved that the space \( (B, \rho) \) is hyperbolic. We present a proof of this result in the appendix.

A set in \( B \) is called bounded if it is contained in some \( \rho \)-ball, or equivalently in a multiple \( rB \) of the operator ball with \( r < 1 \). So a set is bounded if and only if it is separated from the boundary of \( B \) in the sense of Section 1.

The following lemma is a special case of a more general result proved in [6, Theorem IV.2.2].

**Lemma 4.1.** On any bounded set the hyperbolic metrics is equivalent to the operator norm.
5 WOT-topology

As before, let $\mathcal{B}$ be the unit ball of the space of operators from $K$ to $H$. We suppose that $K$ is finite-dimensional, $\dim K = n$, and that $H$ is separable. We consider biholomorphic maps on $\mathcal{B}$. By WOT we denote the weak operator topology (see [5, p. 476]). Because of the separability, the restriction of this topology to $\mathcal{B}$ is metrizable, so in our arguments we may consider only sequences, not nets.

**Lemma 5.1.** If $K$ is finite-dimensional and $H$ is separable then all biholomorphic maps of $\mathcal{B}$ are WOT-continuous.

*Proof.* Let us firstly show that all Möbius transforms $M_B$ are WOT-continuous (this was noticed and used already in the paper of Krein [11]). Indeed let $B \in \mathcal{B}$ be fixed, then the map $\varphi : X \mapsto 1 + B^*X$ from $(\mathcal{B}, \text{WOT})$ to $(L(K, K), \text{WOT})$. Moreover, since $K$ is finite-dimensional, $\varphi$ remains continuous if instead of WOT we endow $L(K, K)$ with its norm topology. The map $T \mapsto T^{-1}$ is norm continuous on the group of invertible operators on $K$. Hence the map $\psi : X \mapsto (1 + B^*X)^{-1}$ is continuous from $(\mathcal{B}, \text{WOT})$ to $L(K, K)$ with its norm topology.

It follows that the map $\omega : X \mapsto (X + B)(1 + B^*X)^{-1}$ is continuous from $(\mathcal{B}, \text{WOT})$ to $(\mathcal{B}, \text{WOT})$. Indeed, if $X_n \to X$, then $\omega(X_n) - \omega(X) = (X_n + B)(\psi(X_n) - \psi(X)) + (X_n - X)\psi(X)$, where $\psi$ was defined above. The first summand tends to zero in norm while the second one tends to zero in WOT.

By a result of Harris [7], if a biholomorphic map of $\mathcal{B}$ preserves the point 0, then it coincides with the restriction to $\mathcal{B}$ of an isometric linear map $h : L(K, H) \to L(K, H)$. Since $K$ is finite-dimensional, the WOT-topology on $L(K, H)$ coincides with the weak topology (indeed $L(K, H)$ is linearly homeomorphic to the direct sum of $n$ copies of $H$); since any bounded linear map is weakly continuous, $h$ is WOT-continuous. On the other hand, if $\varphi$ is a biholomorphic map of $\mathcal{B}$ and $A = \varphi(0)$ then $\psi = M_{-A} \circ \varphi$ is a biholomorphic map preserving 0. Hence $\psi$ is an isometric linear map and $\varphi = M_{-A} \circ \psi = M_A \circ \psi$ is a composition of two WOT-continuous maps. Thus $\varphi$ is WOT-continuous.

**Corollary 5.2.** If $\dim K < \infty$ and $H$ is separable, then each ball $E_{A,r}$ is WOT-compact.

*Proof.* Since there is a Möbius transform that maps $E_{A,r}$ onto $E_{0,r}$, and since all Möbius transforms are WOT-continuous, it suffices to consider the case $A = 0$. But $E_{0,r}$ is a usual closed operator ball; its WOT-compactness follows from the Banach-Alaoglu theorem.

6 Restricted normal structure of $\mathcal{B}$

The purpose of this section is to show that in the case when $\dim K < \infty$ and $H$ is separable, the (open) operator ball $\mathcal{B}$ with the metric (4.2) has a restricted form of normal structure in the sense that WOT-compact $\rho$-convex subsets in it have non-diametral points. As we already mentioned $\mathcal{B}$ with the metric (4.2) is a hyperbolic space (see Section 10).
assumptions on $K$ and $H$ imply that $B$ is separable in the norm-topology and hence, by Lemma 4.1, with respect to $\rho$.

**Theorem 6.1.** Let $K$ be finite dimensional and $H$ be separable. Let $M$ be a weakly compact, $\rho$-convex subset of $B$ endowed with its hyperbolic metric. If $M$ is not a singleton, then $M$ contains a non-diametral point.

**Proof.** Let $\alpha = \text{diam} M > 0$. Assume the contrary, that is, all points in $M$ are diametral. By Lemma 3.1, there is a sequence $\{A_n\}$ in $M$ such that $\lim_{n \to \infty} \rho(A_n, X) = \alpha$ for each $X \in M$.

Since $M$ is weakly compact, the sequence $\{A_n\}_{n=1}^\infty$ contains a weakly convergent subsequence. Let $W$ be its limit, we have $W \in M$ (since $M$ is weakly compact).

Throughout this proof we will not change our notation after passing to a subsequence.

Since $W \in M$ we get

$$\lim_{n \to \infty} \rho(W, A_n) = \alpha. \quad (6.1)$$

We will get a contradiction by proving

$$\sup_{n,m} \rho(A_n, A_m) > \alpha. \quad (6.2)$$

We may assume without loss of generality that $W = 0$ (we can consider a Möbius transformation which maps $W$ to 0, it is a $\rho$-isometry and weak homeomorphism).

Let $\beta = \tanh \alpha$. Then (6.1) leads to $\lim_{n \to \infty} ||A_n|| = \beta$ and it suffices to show that

$$\sup_{n,m} ||M_{A_m}(-A_n)|| > \beta. \quad \text{if} \ \varepsilon > 0 \text{ is small enough.}$$

Since $K$ is finite dimensional and $A_n \in L(K, H)$, we can select a strongly convergent subsequence in the sequence $\{A_n^*, A_n\}$. Assume that $A_n^* A_n \to P$, where $P \in L(K, K)$. It is clear that $P \geq 0$ and $||P|| = \beta^2$.

Choose $\varepsilon > 0$ and fix a number $m$ with $||A_m^* A_m - P|| < \varepsilon$. For brevity, denote $A_m^* A_m$ by $Q$. We prove that $\lim_{n \to \infty} ||M_{A_m}(-A_n)|| > \beta$ if $\varepsilon > 0$ is small enough. By the definition,

$$M_{A_m}(-A_n) = (1 - A_m A_m^*)^{-1/2} (A_m - A_n) (1 - A_m^* A_n)^{-1} (1 - A_m^* A_m)^{1/2}. \quad (6.3)$$

Since $A_m^*$ is of finite rank $A_m^* A_m \to 0$ in the norm topology. Hence $\lim_{n \to \infty} ||M_{A_m}(-A_n)|| = \lim_{n \to \infty} ||T_n||$ where

$$T_n = (1 - A_m A_m^*)^{-1/2} (A_m - A_n) (1 - A_m^* A_m)^{1/2} = A_m - (1 - A_m A_m^*)^{-1/2} A_n (1 - A_m^* A_m)^{1/2}.$$

It follows from the identity

$$(1 - t)^{-1/2} - 1 = \frac{t}{(1-t)(1+(1-t)^{-1/2})}$$

7
that the operator \((1 - A_m A_m^*)^{-1/2}\) is a finite rank perturbation of the identity operator. Since \(A_n \to 0\) in WOT, we obtain that \(\|T_n - S_n\| \to 0\), where \(S_n = A_m - A_n (1 - A_m^* A_m)^{1/2}\).

Denote \(A_n (1 - A_m^* A_m)^{1/2}\) by \(B_n\). Since \(B_n \to 0\) in WOT, the sequence

\[
(A_m - B_n)^* (A_m - B_n) - A_m^* A_m - B_n^* B_n = -A_m^* B_n - B_n^* A_m
\]

tends to zero in norm topology. Furthermore,

\[
B_n^* B_n = (1 - Q)^{1/2} A_n^* A_n (1 - Q)^{1/2}
\]

tends in norm topology to \((1 - Q)^{1/2} P (1 - Q)^{1/2}\). Therefore

\[
(A_m - B_n)^* (A_m - B_n) \to Q + (1 - Q)^{1/2} P (1 - Q)^{1/2}.
\]

Since \(\|P - Q\| < \varepsilon\), we have that

\[
\|Q + (1 - Q)^{1/2} P (1 - Q)^{1/2} - (Q + (1 - Q)Q)\| < \varepsilon.
\]

The inequalities

\[
\beta^2 - \varepsilon \leq \|Q\| \leq \beta^2
\]

imply

\[
\|Q + (1 - Q)Q\| \geq 2\beta^2 - \beta^4 - 2\varepsilon,
\]

whence

\[
\lim_{n \to \infty} \|S_n^* S_n\| = \lim_{n \to \infty} \|(A_m - B_n)^* (A_m - B_n)\| \geq 2\beta^2 - \beta^4 - 3\varepsilon > \beta^2,
\]

if \(\varepsilon\) is sufficiently small.

\[\Box\]

## 7 Fixed points

The main purpose of this section is to establish the existence of a common fixed point for an elliptic group \(G\) of biholomorphic transformations of the operator ball \(\mathcal{B}\). As is shown in Section 10 a biholomorphic transformation of \(\mathcal{B}\) is a bijective isometric transformation of the metric space \((\mathcal{B}, \rho)\) which maps the set \(\mathcal{M}\) onto itself (and hence segments onto segments).

**Lemma 7.1.** If \(G\) is an elliptic group of biholomorphic transformations of \(\mathcal{B}\), then there is a non-empty WOT-compact \(\rho\)-convex \(G\)-invariant subset of \(\mathcal{B}\).

**Proof.** Let \(A \in \mathcal{B}\) be such that the orbit \(G(A) := \{g(A) : g \in G\}\) is bounded. Therefore \(G(A)\) is contained in some closed ball \(E_{a,r}\). Let \(M\) be the intersection of all closed balls containing \(G(A)\). It is clear that this intersection is non-empty (it contains \(G(A)\), WOT-compact and \(\rho\)-convex (as an intersection of WOT-compact \(\rho\)-convex sets). It remains to check that it is \(G\)-invariant. To see this it suffices to observe that each element \(g \in G\) maps the set of balls containing \(G(A)\) bijectively onto itself. \[\Box\]
Lemma 7.2. Let $G$ be an elliptic group of biholomorphic transformations of $\mathcal{B}$. Let $M$ be a minimal WOT-compact $\rho$-convex $G$-invariant subset in $(\mathcal{B}, \rho)$. Then $M$ is a singleton.

Proof. We use the approach suggested in [4]. Assume the contrary, let $\text{diam} M = \alpha > 0$. By Theorem 6.1 $M$ contains a non-diametral point $N$, so that $M \subset \{A : \rho(A, N) \leq \delta\}$ for some $\delta < \alpha$. Consider the set

$$O = \bigcap_{B \in M} E_{B,\delta}.$$ 

The set $O$ is non-empty because $N \in O$. The set $O$ is weakly compact and $\rho$-convex since each of the balls $E_{B,\delta}$ is weakly compact and $\rho$-convex. The set $O$ is a proper subset of $M$ since $M$ has diameter $\alpha > \delta$.

Since $G$ is a group of isometric transformations and $M$ is invariant under each element of $G$, the action of $G$ on $M$ is by isometric bijections. Therefore $O$ is $G$-invariant. We get a contradiction with the minimality of $M$. \hfill $\Box$

Proof of Theorem 1.1. The implication (i) $\Rightarrow$ (ii) is obvious. On the other hand if $G(X_0)$ is separated from the boundary, for some $X_0 \in \mathcal{B}$ then $\sup_{g \in G} \rho(0, g(X_0)) < \infty$ whence, for each $X \in \mathcal{B}$, $\sup_{g \in G} \rho(0, g(X)) \leq \sup_{g \in G} (\rho(0, g(X_0)) + \rho(g(X_0), g(X))) = \sup_{g \in G}(\rho(0, g(X_0)) + \rho(X_0, X)) < \infty$. This means that the orbit $G(X)$ is separated from the boundary. We proved that (i) $\Leftrightarrow$ (ii).

The implication (i) $\Rightarrow$ (iv) can be derived from Lemmas 7.1 and 7.2 as follows. It is clear that families of WOT-compact $\rho$-convex $G$-invariant sets with the finite intersection property have non-empty intersections which are also WOT-compact $\rho$-convex and $G$-invariant. Therefore, by the Zorn Lemma, there is a minimal non-empty WOT-compact $\rho$-convex $G$-invariant set $M_0$. By Lemma 7.2, $M_0$ is a singleton and (iv) is proved.

If (iv) is true and $A$ is a fixed point of $G$ then, $G_1 = M_{-A}GM_A$ is a group of biholomorphic maps of $\mathcal{B}$ preserving 0. Hence it consists of restrictions to $\mathcal{B}$ of isometric linear maps (see the beginning of Section 4 in this connection). Thus $G_1$ is equicontinuous.

Note that each Möbius transform is a Lipschitz map: $\|M_A(X) - M_A(Y)\| \leq C\|X - Y\|$ for each $X, Y \in \mathcal{B}$, where the constant $C > 0$ depends on $A$. Indeed setting $F(X) = (A + X)(1 + A^*X)^{-1}$ and $D = (1 - \|A\|)^{-1}$ we have

$$\|F(X) - F(Y)\| = \|(A + X)((1 + A^*X)^{-1} - (1 + A^*Y)^{-1}) + (X - Y)(1 + A^*Y)^{-1}\|$$

$$= \|(A + X)(1 + A^*X)^{-1}A^*(Y - X)(1 + A^*Y)^{-1} + (X - Y)(1 + A^*Y)^{-1}\|$$

$$\leq 2D^2\|X - Y\| + D\|X - Y\| \leq 3D^2\|X - Y\|.$$ 

Hence

$$\|M_A(X) - M_A(Y)\| = \|(1 - AA^*)^{-1/2}(F(X) - F(Y))(1 - A^*A)^{1/2}\|$$

$$\leq D^{3/2}\|F(X) - F(Y)\| \leq 3D^{3/2}\|X - Y\|.$$ 

Since $G = M_AG_1M_{-A}$ and the maps $M_A, M_{-A}$ are Lipschitz, $G$ is also equicontinuous. We proved that (iv) $\Rightarrow$ (iii).
Let now (iii) hold, we have to prove (ii). We will show that the orbit of 0 is separated from the boundary. Assuming the contrary we get that for any $\delta > 0$ there is $g \in G$ with $\|g(0)\| > 1 - \delta$. Let $A = g(0)$; we may assume that $\delta < 1/2$ so $\|A\| > 1/2$.

By the already mentioned result of [7], $g = M_A \circ h$ where $h$ is a linear isometry. Let $P$ be the spectral projection of $T = A^*A$ corresponding to the eigenvalue $\|T\| = \|A\|^2$ (recall that $T$ is an operator in a finite dimensional space). Then

$$\|(1 - T)P\| = 1 - \|T\| \leq 2(1 - \|A\|) < 2\delta.$$ 

Set $X_1 = 0$, $X_2 = h^{-1}(\frac{1}{2}AP)$. Then $\|X_2 - X_1\| = \frac{1}{2}\|AP\| = \|A\|/2 > 1/4$.

On the other hand

$$\|g(X_2) - g(X_1)\| = \left\| M_A \left( \frac{1}{2}AP \right) - M_A(0) \right\| $$

$$= \left\| (1 - AA^*)^{-1/2} \left( \frac{1}{2}AP + A \right) \left( 1 + \frac{1}{2}A^*AP \right)^{-1} (1 - A^*A)^{1/2} - A \right\|$$

$$= \left\| A(1 - T)^{-1/2} \left( \frac{1}{2}P + 1 \right) \left( 1 + \frac{1}{2}TP \right)^{-1} (1 - T)^{1/2} - A \right\|$$

$$= \left\| A \left( \frac{1}{2}P + 1 \right) \left( 1 + \frac{1}{2}TP \right)^{-1} - A \right\| = \left\| \frac{1}{2}A(1 - T)P \left( 1 + \frac{1}{2}TP \right)^{-1} \right\|$$

$$\leq \frac{1}{2}\|A\|(1 - T)P < \frac{1}{2}2\delta = \delta.$$

This contradicts to the assumption of equicontinuity. Indeed for each $\delta$ we get points $Y_i = g(X_i)$ with $\|Y_1 - Y_2\| < \delta$ and $\|g^{-1}(Y_1) - g^{-1}(Y_2)\| > 1/4$. Thus (ii) holds. \qed

### 8 Orthogonalization

**Theorem 8.1.** If a bounded representation $\pi$ of a group $G$ on a Hilbert space $\mathcal{H}$ preserves a quadratic form $\eta$ with finite number of negative squares then it is similar to a unitary representation.

**Proof.** By our assumptions, $\mathcal{H} = H_1 \oplus H_2$, $\dim(H_2) < \infty$, and $\eta(x) = \|Px\|^2 - \|Qx\|^2$ where $P, Q$ are the projections onto $H_1$ and $H_2$ respectively. We write $H_1 = H$ and $H_2 = K$, for brevity.

We will relate to each invertible operator $T$ on $\mathcal{H}$ preserving the form $\eta$ a biholomorphic map $w_T$ of $\mathcal{B}$ in such a way that

$$w_{T_1T_2} = w_{T_1} \circ w_{T_2}. \quad (8.1)$$

Let us call a subspace $L$ of $\mathcal{H}$ positive (negative) if $\eta(y) > 0$ (respectively $\eta(y) < 0$) for all non-zero $y \in L$. Since each negative subspace $L$ is finite-dimensional, there is $\varepsilon > 0$ such that

$$\eta(y) \leq -\varepsilon\|y\|^2$$

for all non-zero $y \in L$.  

10
The supremum of all such \( \varepsilon \) is called the \textit{degree of negativeness} of \( L \) and is denoted by \( \varepsilon(L) \).

For each operator \( A \in \mathcal{B} \), the set
\[
L(A) = \{ Ax \oplus x : x \in K \}
\]
is a negative subspace of \( \mathcal{H} \). Furthermore the condition
\[
\eta(y) \leq -\varepsilon \| y \|^2, \text{ for all } y \in L(A)
\]
means that
\[
-\| x \|^2 + \| Ax \|^2 \leq -\varepsilon (\| x \|^2 + \| Ax \|^2)
\]
for all \( x \in K \). That is
\[
\varepsilon \leq \frac{1 - \| A \|^2}{1 + \| A \|^2}.
\]
It follows that the degree of negativeness of \( L(A) \) is related to \( \| A \| \) by the equality
\[
\varepsilon(L(A)) = \frac{1 - \| A \|^2}{1 + \| A \|^2}. \tag{8.2}
\]

Since \( \dim(L(A)) = \dim(K) \), \( L(A) \) is a maximal negative subspace in \( \mathcal{H} \). Indeed if some subspace \( M \) of \( \mathcal{H} \) strictly contains \( L(A) \) then its dimension is greater than codimension of \( H \), whence \( M \cap H \neq \{0\} \). But all non-zero vectors in \( H \) are positive.

Conversely, each maximal negative subspace \( Q \) of \( \mathcal{H} \) coincides with \( L(A) \), for some \( A \in \mathcal{B} \). Indeed, since \( Q \cap H = \{0\} \), there is an operator \( A : K \to H \) such that each vector of \( Q \) is of the form \( Ax \oplus x \). Since \( Q \) is negative, we have \( \eta(Ax \oplus x) = \| Ax \|^2 - \| x \|^2 < 0 \), and therefore \( \| A \| < 1 \), so \( A \in \mathcal{B} \). Thus \( Q \subseteq L(A) \); and, by maximality, \( Q = L(A) \).

It is easy to see that the map \( A \to L(A) \) from \( \mathcal{B} \) to the set \( \mathcal{E} \) of all maximal negative subspaces is injective and therefore bijective.

Now we can define \( w_T \). Indeed, if a subspace \( L \) of \( \mathcal{H} \) is maximal negative then its image \( TL \) under \( T \) is also maximal negative (because \( T \) is invertible and preserves \( \eta \)). Hence, for each \( A \in \mathcal{B} \), there is \( B \in \mathcal{B} \) such that \( L(B) = TL(A) \). We let \( w_T(A) = B \).

The equality (8.1) follows easily because \( L(w_{T_1}(w_{T_2}(A))) = T_1L(w_{T_2}(A)) = T_1T_2L(A) = L(w_{T_1T_2}(A)) \) and the map \( A \to L(A) \) is injective.

Our next goal is to check that \( w_T \) is biholomorphic. Since \( w_T^{-1} = w_{T^{-1}} \) it suffices to show that \( w_T \) is holomorphic.

Let \( T = (T_{ij})_{i,j=1}^2 \) be the matrix of \( T \) with respect to the decomposition \( \mathcal{H} = H_1 \oplus H_2 \). Then \( T(Ax \oplus x) = (T_{11}Ax + T_{12}x) \oplus (T_{21}Ax + T_{22}x) \). Since \( T(Ax \oplus x) \in L(w_T(A)) \), we conclude that
\[
w_T(A)(T_{21}Ax + T_{22}x) = T_{11}Ax + T_{12}x.
\]
Thus
\[
w_T(A) = (T_{11}A + T_{12})(T_{21}A + T_{22})^{-1}. \tag{8.3}
\]
This shows that $w_T$ is a holomorphic map on $B$.

Suppose now that $\pi$ is a bounded representation of a group $G$ on $\mathcal{H}$ preserving $\eta$. Then $W = \{w_{\pi(g)} : g \in G\}$ is a group of biholomorphic maps of $B$. Moreover since $\pi$ is bounded, the group $W$ is elliptic. To see this, note that for each negative subspace $L$, one has

$$\eta(y) \leq -\epsilon(L)\|y\|^2$$

for all $y \in L$.

If $T$ is an invertible operator preserving $\eta$ then $T^{-1}x \in L$, for each $x \in TL$, whence

$$\eta(x) = \eta(T^{-1}x) \leq -\epsilon(L)\|T^{-1}x\|^2 \leq -\epsilon(L)\|T\|^{-2}\|x\|^2.$$

Thus

$$\epsilon(TL) \geq \epsilon(L)\|T\|^{-2}.$$

For $L = L(A)$, $TL = L(w_T(A))$. This gives

$$\frac{1 - \|w_T(A)\|^2}{1 + \|w_T(A)\|^2} \geq \frac{\|T\|^{-2}1 - \|A\|^2}{1 + \|A\|^2}$$

if one takes into account (8.2). Thus, if $\|\pi(g)\| \leq C$ for all $g \in G$, then

$$\frac{1 - \|w_{\pi(g)}(A)\|^2}{1 + \|w_{\pi(g)}(A)\|^2} \geq C^{-2}\frac{1 - \|A\|^2}{1 + \|A\|^2}.$$

Therefore

$$1 - \|w_{\pi(g)}(A)\|^2 \geq C^{-2}\frac{1 - \|A\|^2}{1 + \|A\|^2}$$

and

$$\sup_{g \in G}\|w_{\pi(g)}(A)\| < 1$$

for each $A \in B$.

By Theorem 1.1, there is $D \in B$ with $w_{\pi(g)}(D) = D$ for all $g \in G$. Hence $\pi(g)L(D) = L(D)$ for all $g \in G$.

Let $U$ be an operator on $\mathcal{H}$ with the matrix $(U_{ij})$ where $U_{11} = (1_H - DD^*)^{-1/2}$, $U_{12} = -D(1_K - D^*D)^{-1/2}$, $U_{21} = -D^*(1_H - DD^*)^{-1/2}$, $U_{22} = (1_K - D^*D)^{-1/2}$. It can be checked that $U$ preserves $\eta$ and maps $L(D)$ onto $K$. Then all operators $\tau(g) = U\pi(g)U^{-1}$ preserve $\eta$, and the subspace $K$ is invariant for them. It follows that $H$ is also invariant for operators $\tau(g)$. Hence these operators preserve the scalar product on $\mathcal{H}$. Thus $g \mapsto \tau(g)$ is a unitary representation similar to $\pi$.

It should be noted that Theorem 8.1 does not extend to the case when $\eta$ has infinite number of negative (and positive) squares, that is, to the case that both $H_1$ and $H_2$ are infinite-dimensional [16].
9  J-unitary operators on Pontryagin spaces

The Pontryagin space is a linear space \( \mathcal{H} \) supplied with an indefinite scalar product \( x, y \rightarrow [x, y] \) which has a finite number of negative squares. More precisely this means that one can choose a usual scalar product \( x, y \rightarrow (x, y) \) with respect to which \( \mathcal{E} \) is a Hilbert space and \( [x, y] = (Jx, y) \), where \( J \) is a selfadjoint involutive operator on this Hilbert space with \( \text{rank}(1 - J) < \infty \). An invertible operator \( T \) on \( \mathcal{E} \) is called \( J \)-unitary if \( [Tx, Ty] = [x, y] \) for all \( x, y \in \mathcal{E} \).

It should be noted that the terminology does not seem to be successful because the choice of the operator \( J \) and the corresponding scalar product is not unique while the set of \( J \)-unitary operators is completely determined by the original indefinite scalar product \( [\cdot, \cdot] \). However, this terminology is widely used (see, for example, [1], [10] and references therein).

It is important that all scalar products defining \( [\cdot, \cdot] \) via \( J \)-operators are equivalent, so one can speak, for example, about boundedness of a set of operators, without indicating which scalar product is chosen.

A subspace \( X \subset \mathcal{E} \) is called positive (negative) if \( [x, x] > 0 \) (respectively \( [x, x] < 0 \)) for all \( x \in X \). A dual pair of subspaces in \( \mathcal{E} \) is a pair \( Y, Z \) where \( Y \) is a positive subspace, \( Z \) is a negative subspace and \( Y + Z = \mathcal{E} \). The study of dual pairs invariant for a given set of \( J \)-unitary operators was started by Sobolev and intensively developed by Pontryagin, Krein, Phillips, Naimark and other prominent mathematicians.

The previous theorem on the orthogonalization of representations implies the following result.

**Corollary 9.1.** A group of \( J \)-unitary operators on a Pontryagin space has an invariant dual pair if and only if it is bounded.

**Proof.** Choose a scalar product \( (\cdot, \cdot) \) and the corresponding operator \( J \). Denote by \( \mathcal{H} \) the Hilbert space \( (\mathcal{E}, (\cdot, \cdot)) \). Since \( J \) is an Hermitian involutive operator, there are orthogonal subspaces \( H, K \) of \( \mathcal{H} \) such that \( J = P_H - P_K \). By our assumption on \( J \), the subspace \( K \) is finite-dimensional.

Let \( G \) be a group of \( J \)-unitary operators. If it is bounded, then the identity map can be regarded as a bounded representation of \( G \) on \( \mathcal{H} \). Moreover it preserves the form \( \eta(x) = [x, x] \). Since it has a finite number of negative squares, Theorem 8.1 implies that there is an invertible operator \( V \) such that the representation \( \tau(g) = T^{-1}gT \) is unitary. It follows from [10, Theorem 5.8] that \( G \) has an invariant dual pair of subspaces.

For completeness we include the proof of this fact. Passing to adjoints in the equality \( T\tau(g) = gT \) and taking into account that \( g^* = Jg^{-1}J \), \( \tau(g)^* = \tau(g^{-1}) \) we obtain that \( \tau(g^{-1})T^* = T^*Jg^{-1}J \). Using this identity for \( g \) instead of \( g^{-1} \) and multiplying both sides by \( JT \) we get:

\[
\tau(g)T^*JT = T^*JgJJT = T^*JgT = T^*JT\tau(g).
\]

Thus the invertible selfadjoint operator \( R = T^*JT \) commutes with the group \( \tau(G) \) of unitary operators. It follows that its spectral subspaces \( H_1 \) and \( K_1 \) corresponding to positive and negative parts of spectrum are invariant for \( \tau(G) \). Note that \( (Rx, x) > 0 \) for \( x \in H_1 \).
\( T^{-1}H \setminus \{0\} \) and \( (Rx, x) < 0 \) for \( x \in T^{-1}K \setminus \{0\} \). It follows that \( \dim K_1 = \dim K \). Now the subspaces \( H_2 = TH_1 \) and \( K_2 = TK_1 \) form an invariant dual pair for \( G \).

The converse implication is simple. If \( G \) has an invariant dual pair \( H, K \) then the scalar product \( (h_1 + k_1, h_2 + k_2) = [h_1, h_2] - [k_1, k_2] \) is invariant for \( G \). Thus \( G \) is a group of unitary operators on \( \mathcal{H} = (\mathcal{E}, (\cdot, \cdot)) \), hence it is bounded.

As a consequence we obtain the following result proved in [16]:

**Corollary 9.2.** A \( J \)-symmetric representation of a unital \( C^* \)-algebra on a Pontryagin space is similar to a \( * \)-representation.

For a proof it suffices to notice that restricting the representation to the unitary group of the \( C^* \)-algebra we obtain a bounded group of \( J \)-unitary operators.

## 10 Appendix: Hyperbolicity of \( \mathcal{B} \) (after Itai Shafrir)

For any bounded domains \( D_1, D_2 \) of complex Banach spaces we denote by \( \text{Hol}(D_1, D_2) \) the set of all holomorphic maps from \( D_1 \) to \( D_2 \). If \( D_1 = D_2 = D \) then \( \text{Hol}(D_1, D_2) \) is a semigroup with respect to the composition, and by \( \text{Aut}(D) \) we denote the set of all its invertible elements (biholomorphic automorphisms of \( D \)). The group \( \text{Aut}(\mathcal{B}) \) acts transitively on \( \mathcal{B} \). Indeed, for each \( A \in \mathcal{B} \) the Möbius transform \( M_A \) is biholomorphic and sends 0 to \( A \).

As usually the Carathéodory metric on \( \mathcal{B} \) is defined by the equality:

\[
\alpha_B(A, B) = \sup_{f \in \text{Hol}(\mathcal{B}, \Delta)} \omega(f(A), f(B))
\]

where \( \Delta \) is the unit disk and \( \omega \) is the Poincaré distance:

\[
\omega(z_1, z_2) = \text{tanh}^{-1} \left( \frac{z_1 - z_2}{1 - \overline{z_1}z_2} \right).
\]

As it was mentioned in Section 4, \( \alpha_B \) coincides with the metric \( \rho \) defined by the formula (4.2). Clearly \( \alpha_B \) is invariant under biholomorphic maps of \( \mathcal{B} \).

We shall prove that \( \mathcal{B} \) is a hyperbolic space with respect to this metric.

Furthermore the differential Carathéodory metrics on \( \mathcal{B} \) is defined by

\[
\alpha(A, V) = \sup_{f \in \text{Hol}(\mathcal{B}, \Delta)} \frac{|\mathcal{D}f(A)V|}{1 - |f(A)|^2}
\]

for all \( A \in \mathcal{B}, V \in L(K, H) \), where \( \mathcal{D}f(A) \) is the differential of \( f \) in \( A \) (see [6], where \( \alpha \) is denoted by \( \gamma_B \)).

**Lemma 10.1.** For each \( A \in \mathcal{B}, V \in L(K, H) \)

\[
\mathcal{D}M_B(A)V = (1 - BB^*)^{1/2}(1 + AB^*)^{-1}V(1 + B^*A)^{-1}(1 - B^*B)^{1/2}.
\]

(10.2)

In particular,

\[
\mathcal{D}M_B(0)V = (1 - BB^*)^{1/2}V(1 - B^*B)^{1/2}.
\]
Proof. By definition, $M_B(X) = (1 - BB^*)^{-1/2}(B + X)(1 + B^*X)^{-1}(1 - B^*B)^{1/2}$. We have to calculate the coefficient $c$ of $t$ in the Taylor decomposition of the function $t \to M_B(A + tV)$. For this, note that if $P$ is an invertible operator then $(P + tQ)^{-1} = P^{-1} - tP^{-1}QP^{-1} + o(t)$.

It follows immediately that

\[
c = (1 - BB^*)^{-1/2}(1 + B^*A)^{-1} - (B + A)(1 + B^*A)^{-1}B^*V(1 + B^*A)^{-1}(1 - B^*B)^{1/2}
\]

\[
= (1 - BB^*)^{-1/2}(1 - (B + A)(1 + B^*A)^{-1}B^*)V(1 + B^*A)^{-1}(1 - B^*B)^{1/2}
\]

\[
= (1 - BB^*)^{-1/2}(1 - (B + A)B^*(1 + AB^*)^{-1})V(1 + B^*A)^{-1}(1 - B^*B)^{1/2}
\]

\[
= (1 - BB^*)^{-1/2}(1 + AB^*)^{-1}V(1 + B^*A)^{-1}(1 - B^*B)^{1/2}
\]

\[
= (1 - BB^*)^{-1/2}(1 + AB^* - (B + A)B^*)V(1 + B^*A)^{-1}(1 - B^*B)^{1/2}
\]

\[
= (1 - BB^*)^{-1/2}(1 + AB^*)^{-1}V(1 + B^*A)^{-1}(1 - B^*B)^{1/2}.
\]

\[
\square
\]

Lemma 10.2. $\alpha(A, V) = \|(1 - AA^*)^{-1/2}V(1 - A^*A)^{-1/2}\|$ for all $A \in B$ and $V \in L(K, H)$.

Proof. By [6, Lemma V.1.5]

\[
\alpha(0, V) = \|V\|.
\]

Let now $A$ be arbitrary. Then by [6, Proposition V.1.2]

\[
\alpha(M_A(0), D M_A(0) X) = \alpha(0, X) = \|X\|.
\]

On the other hand, by Lemma 10.1,

\[
\alpha(M_A(0), D M_A(0) X) = \alpha(A, (1 - AA^*)^{1/2}X(1 - A^*A)^{1/2}).
\]

Setting now $V = (1 - AA^*)^{1/2}X(1 - A^*A)^{1/2}$, we obtain $X = (1 - AA^*)^{-1/2}V(1 - A^*A)^{-1/2}$ and hence $\alpha(A, V) = \|(1 - AA^*)^{-1/2}V(1 - A^*A)^{-1/2}\|$.

\[
\square
\]

For any bounded operator $D$, set $D^{(1)} = D$, $D^{(3)} = DD^*D$, $D^{(5)} = DD^*DD^*D$, \ldots, $D^{(2k+1)} = (DD^*)^k D$.

Let

\[
Th D = \sum_{n=0}^{\infty} a_{2n+1}D^{(2n+1)}
\]

(10.3)

where $a_j$ are the Taylor coefficients of $\tanh t$, i.e., $\tanh t = \sum_{n=0}^{\infty} a_{2n+1}t^{2n+1}$.

It follows from the definition that $Th D = \tanh(D)$ if $D$ is selfadjoint.

If $D = JD$ is the polar decomposition of $D$ (that is, $|D| = (D^*D)^{1/2}$ and $J$ is a partial isometry such that $(J^*J)|D| = |D|(J^*J) = |D|$), then

\[
D^{(2n+1)} = J|D|^{2n+1},
\]

and hence

\[
Th D = J\tanh |D|.
\]

15
On the other hand, we can write $D = |D^*|J$, where $|D^*| = J|D|J^* = (DD^*)^{1/2}$, therefore

$$Th \ D = (\tanh |D^*|)J.$$ 

For the space $(B, \rho)$ we define the set $\mathcal{M}$ of lines as follows: for $A \in B$, $D \in \partial B$ (i.e., $|D| = 1$) we let

$$\gamma_{A,D} = \{\gamma_{A,D}(t) := M_A(Th(tD)) : t \in \mathbb{R}\} \quad (10.4)$$

and set

$$\mathcal{M} = \{\gamma_{A,D} : A \in B, D \in \partial B\}.$$ 

**Proposition 10.3.** $\gamma_{A,D}$ is a metric line.

**Proof.** It is enough to show that $\rho(\gamma_{A,D}(s), \gamma_{A,D}(t)) = |s - t|$. Since $\rho$ is invariant with respect to $M_A$ we can assume that $A = 0$. We have $\rho(\gamma_{0,D}(s), \gamma_{0,D}(t)) = \tanh^{-1}|M_B(Th(tD))|$, where $B = -Th(sD)$. Using polar decomposition $D = J|D|$ we have that $Th(tD) = J\tanh(t|D|)$, $Th(tD)^*Th(sD) = \tanh(t|D|)\tanh(s|D|)$, whence

$$M_B(Th(tD)) = (1 - Th(sD)Th(sD)^*)^{-1/2}(Th(tD) - Th(sD))$$

$$(1 - Th(sD)^*Th(sD))^{-1}(1 - Th(sD)^*Th(sD))^{1/2}$$

$$= J(1 - \tanh^2(s|D|))^{-1/2}J^*J(1 - \tanh(t|D|) - \tanh(s|D|))$$

$$(1 - \tanh(s|D|))\tanh(t|D|))^{-1}(1 - \tanh^2(s|D|))^{1/2}$$

$$= J\tanh((t - s)|D|) = Th((t - s)D)$$

giving the statement.  

We have to prove that $\gamma_{A,D}(t)$ is a metric curve, in the sense that the metric of its derivation equals 1, i.e., $\alpha(\gamma(t), \gamma'(t)) = 1$.

**Lemma 10.4.** Let $\gamma(t) = Th(tD), D \in \partial B$. Then

$$\gamma'(t) = D - \gamma(t)D^*\gamma(t). \quad (10.5)$$

**Proof.** We have $\gamma(t) = J\tanh(t|D|)$ and

$$\gamma'(t) = J|D|\cosh(t|D|)^{-2} = D(\cosh(t|D|)^{-2}.$$ 

On the other hand

$$D - \gamma(t)D^*\gamma(t) = D - J\tanh(t|D|)|D|J^*J\tanh(t|D|) = D - D\tanh^2(t|D|) = D(\cosh(t|D|)^{-2}$$

giving (10.5).  

**Lemma 10.5.** Let $\gamma(t) = Th(tD), D \in \partial B$. Then

$$(1 - \gamma\gamma^*)^{-1/2}(D - \gamma D^*\gamma)(1 - \gamma^*\gamma)^{-1/2} = D. \quad (10.6)$$
Proof. Setting $D = J|D|$, we have

$$\gamma^*\gamma = \text{Th}(tD)^*\text{Th}(tD) = \tanh(t|D|)J^*J \tanh(t|D|) = \tanh^2(t|D|).$$

Furthermore

$$\gamma\gamma^* = \tanh(t|D^*|)JJ^* \tanh(t|D^*|) = \tanh^2(t|D^*|).$$

Since

$$D|D| = |D^*|D,$$

we have that

$$Df(|D|) = f(|D^*|D)$$

for any bounded Borel function $f$. Taking $f(x) = 1 - \tanh^2(tx)$, we get

$$D(1 - \gamma^*\gamma) = (1 - \gamma\gamma^*)D.$$

Next

$$D^*\gamma = \gamma^*D$$

because $D^*\text{Th}(tD) = D^*J \tanh(t|D|) = |D| \tanh(t|D|)$ is selfadjoint.

Hence

$$(1 - \gamma\gamma^*)^{-1/2}(D - \gamma D^*\gamma)(1 - \gamma^*\gamma)^{-1/2} = (1 - \gamma\gamma^*)^{-1/2}(1 - \gamma\gamma^*)D(1 - \gamma^*\gamma)^{-1/2} = (1 - \gamma\gamma^*)^{1/2}(1 - \gamma^*\gamma)^{-1/2}D = D.$$

$\square$

**Proposition 10.6.** Let $\gamma(t) = \gamma_{A,D}(t)$, $A \in \mathcal{B}$, $D \in \partial \mathcal{B}$. Then

$$\alpha(\gamma(t), \gamma'(t)) = 1.$$

Proof. It suffices to prove this for $A = 0$, since $\alpha(F(X), D F(X)V) = \alpha(X, V)$ for any $F \in \text{Aut}(\mathcal{B})$, $X \in \mathcal{B}$, $V \in L(H, K)$ (see [6, Proposition V.1.2]), and hence

$$\alpha(M_A(\text{Th}(tD)), (M_A(\text{Th}(tD)))') = \alpha(M_A(\text{Th}(tD)), D M_A(\text{Th}(tD)))(\text{Th}(tD))')$$

$$= \alpha(\text{Th}(tD), (\text{Th}(tD))').$$

Assume therefore $\gamma(t) = \text{Th}(tD)$. By Lemma 10.2 and 10.5 we have

$$\alpha(\gamma(t), \gamma'(t)) = \|(1 - \gamma\gamma^*)^{-1/2}(D - \gamma D^*\gamma)(1 - \gamma^*\gamma)^{-1/2}\| = \|D\| = 1.$$

$\square$

The next step is to prove that the family $\mathcal{M}$ of all lines is invariant with respect to the biholomorphic maps of $\mathcal{B}$.

**Lemma 10.7.** Let $\eta(t) = M_A(\gamma(t))$ where $\gamma(t) = \text{Th}(tD)$. Then, for each biholomorphic map $h : \mathcal{B} \rightarrow \mathcal{B}$, the curve $h(\eta(t))$ belongs to the family $\mathcal{M}$. 17
Proof. By [8, Theorems 3 and 4], there is a linear isometry $L$ of the space $L(K, H)$ to itself satisfying the condition

$$L(AB^*A) = L(A)L(B)^*L(A) \text{ for all } A, B \in L(K, H)$$

(10.7)

and such that

$$h = M_{h(0)} \circ L = L \circ M_{-h(0)}.$$

It follows from (10.7) (see a remark after [8, Corollary 5]) that

$$L \circ M_A = M_{L(A)} \circ L$$

for all $A \in \mathcal{B}$.

So it suffices to consider the cases $h = L$ and $h = M_B$. Let us firstly prove that $L(\eta(t)) \in \mathcal{M}$. Indeed,

$$L(\eta(t)) = L(M_A(\gamma(t))) = M_{L(A)}(L(\gamma(t))) = M_{L(A)}(L(Th(tD))) = M_{L(A)}(L(Th(tL(D)))) \in \mathcal{M}.$$

Now we have to prove that $M_B(\eta(t)) \in \mathcal{M}$. Applying [8, Theorems 3 and 4] to $h(x) = M_B(M_A(x))$ we get a linear isometry $L$ satisfying (10.7) and such that

$$M_B \circ M_A = M_C \circ L$$

where $C = h(0) = M_B(A)$. Thus

$$M_B(\eta(t)) = M_B(M_A(\gamma(t))) = M_C(L(\gamma(t))) = M_C(Th(tL(D))) \in \mathcal{M}.$$

\[\square\]

Our next goal is to show that for each $A, B \in \mathcal{B}$ there is a unique line in $\mathcal{M}$ which passes through $A, B$.

**Lemma 10.8.** The set of all lines in $\mathcal{M}$ that go through $A$ is $\{\gamma_{A,D} : D \in \partial(\mathcal{B})\}$.

**Proof.** It suffices to assume that $A = 0$. Suppose that a line $\gamma(t) = M_B(Th(tD))$ goes through 0, i.e., $\gamma(s) = 0$ for some $s \in \mathbb{R}$. Then clearly $B = -Th(sD)$. Using the arguments from the proof of Proposition 10.3 we obtain $\gamma(t) = Th((t-s)D)$. Thus $\gamma = \gamma_{0,D}$. \[\square\]

**Corollary 10.9.** For each $A, B \in \mathcal{B}$, there is a unique line in $\mathcal{M}$ that passes through them.

**Proof.** We may assume that $A = 0$. Let $B = J|B|$ be the polar decomposition of $B$ and let $C = \tanh^{-1}|B|/t_0$ for $t_0 > 0$ be such that $||C|| = 1$. Then for $D = JC$ the line $\gamma_{0,D}$ passes through 0 and $B$.

If there are two lines, $\gamma_{0,D_1}$ and $\gamma_{0,D_2}$, going through $B$ then by the above lemma, $B = Th(tD_1) = Th(sD_2)$ for some $t, s \in \mathbb{R}$. We may suppose that $t, s > 0$. Taking polar decompositions of $D_1 = J_1|D_1|$ and $D_2 = J_2|D_2|$ we see that $J_1 = J_2$ and $\tanh(t|D_1|) = \tanh(s|D_2|)$, which imply that $t|D_1| = s|D_2|$. But this clearly shows that the lines coincide. \[\square\]
Lemma 10.10.

\[ \|A\| \leq \|(1 - BB^*)^{-1/2}(A - BA^*B)(1 - B^*B)^{-1/2}\|. \] (10.8)

for each \( A, B \in \mathcal{B} \).

Proof. Consider the polar decomposition \( B = J|B| \). Then \( |B^*| = (BB^*)^{1/2} = J|B||J^* \). Let \( P = \tanh^{-1}(|B^*|) \), and \( Q = \tanh^{-1}(|B|) \). Then

\[ (1 - BB^*)^{-1/2}(A - BA^*B)(1 - B^*B)^{-1/2} = (\cosh P)A(\cosh Q) - (\sinh P)JAJ^*(\sinh Q). \]

For any \( \varepsilon > 0 \), there are unit vectors \( x, y \) such that

\[ \|(\cosh P)A(\cosh Q)x, y\| \geq \|(\cosh P)y\|\|A\|\|(\cosh Q)x\| - \varepsilon. \]

Since \( \|(\cosh P)y\|^2 - \|(\sinh P)y\|^2 = \|y\|^2 \), and \( \|(\cosh Q)x\|^2 - \|(\sinh Q)x\|^2 = \|x\|^2 \) one can find numbers \( a, b \) such that

\[ \|(\sinh P)y\| = \sinh b, \|(\cosh P)y\| = \cosh b, \|(\sinh Q)x\| = \sinh a, \|(\cosh Q)x\| = \cosh a. \]

Hence

\[ \|(\cosh P)A(\cosh Q) - (\sinh P)JAJ^*(\sinh Q)\| \geq (\|(\cosh P)A(\cosh Q) - (\sinh P)JAJ^*(\sinh Q)x, y\| \geq (\cosh b)(\cosh a)\|A\| - \varepsilon - (\sinh b)(\sinh a)\|A\| \geq \cosh(b - a)\|A\| - \varepsilon \geq \|A\| - \varepsilon, \]

giving the statement. \( \Box \)

Lemma 10.11. Let us consider two lines: \( \gamma(t) = M_A(\text{Th}(tC)) \), \( \eta(t) = M_A(\text{Th}(tD)) \). Then

\[ 2\rho(\gamma(s), \eta(s)) \leq \rho(\gamma(2s), \eta(2s)) \] (10.9)

for each \( s > 0 \).

Proof. Since \( \rho \) is invariant with respect to the transformations \( M_A \) we may assume \( A = 0 \). Let \( C(t) \) be a curve \( \gamma_{B,E}(t) \) which joins \( \gamma(2s) \) with \( \eta(2s) \), we assume that \( C(0) = \gamma(2s), C(t_0) = \eta(2s) \) for some \( t_0 > 0 \) (such curve exists by Corollary 10.9). Define now a new curve \( C_1 \) by

\[ C_1 = \text{Th} \left( \frac{1}{2} \text{Th}^{-1}C \right). \]

Then \( C_1(0) = \gamma(s), C_1(t_0) = \eta(s) \) and

\[ C(t) = 2C_1(t)(1 + C_1(t)^*C_1(t))^{-1}. \] (10.10)

As usually we denote by \( L(C_1) \) the length of the curve \( C_1 \): \( L(C_1) = \int_{t_0}^{t_0} \alpha(C_1(t), C_1'(t)) dt. \)

If we could show that

\[ L(C) \geq 2L(C_1) \] (10.11)
for all curves $C$, $C_1$ satisfying (10.10) then we would obtain that

$$\rho(\gamma(2s), \eta(2s)) = L(C) \geq 2L(C_1) \geq 2\rho(\gamma(s), \eta(s))$$

(the first equality follows from Proposition 10.3 and Proposition 10.6, the last inequality holds because the length of any curve is not smaller then the distance between its ends).

Thus our goal is the inequality (10.11). It suffices to show that

$$2\alpha(C_1(t), C'_1(t)) \leq \alpha(C(t), C'(t)).$$

(10.12)

Since

$$2C_1 = C(1 + C_1^* C_1),$$

we have

$$C'(1 + C_1^* C_1) + C(C_1^* C_1 + C_1^* C'_1) = 2C'_1,$$

whence

$$C' = ((2 - CC_1^*)C_1 - CC_1^* C_1)(1 + C_1^* C_1)^{-1}.$$

(10.13)

Since

$$2 - CC_1^* = 2 - 2C_1(1 + C_1^* C_1)^{-1} = 2(1 - C_1 C_1^* (1 + C_1 C_1^* )^{-1}) = 2(1 + C_1 C_1^* )^{-1},$$

substituting this into (10.13) we obtain

$$C' = 2((1 + C_1 C_1^*)^{-1/2} C_1 - C_1 (1 + C_1^* C_1)^{-1} C_1^* (1 + C_1^* C_1)^{-1}) = 2(1 + C_1 C_1^*)^{-1} (C_1 - C_1 C_1^* C_1)(1 + C_1^* C_1)^{-1}.$$

Now it follows from Lemma 10.2 that the inequality (10.11) is equivalent to the following

$$\| (1 - C_1 C_1^*)^{-1/2} C_1^* (1 - C_1 C_1^*)^{-1/2} \|$$

$$\leq \| (1 - CC^* )^{-1/2} (1 + C_1 C_1^*)^{-1} (C_1 - C_1 C_1^* C_1)(1 + C_1^* C_1)^{-1} (1 - C^* C)^{-1/2} \|.$$

(10.14)

But

$$1 - CC^* = 1 - 4C_1(1 + C_1^* C_1)^{-2} C_1^* = 1 - 4C_1 C_1^* (1 + C_1 C_1^* )^{-2}$$

$$= ((1 + C_1 C_1^*)^2 - 4C_1 C_1^*)(1 + C_1 C_1^* )^{-2} = (1 - C_1 C_1^*)^2 (1 + C_1 C_1^*)^{-2}.$$  

Similarly

$$1 - C^* C)^{-1/2} = (1 + C_1 C_1) (1 - C_1 C_1^* )^{-1}.$$

It follows now that (10.14) is equivalent to the inequality

$$\| (1 - C_1 C_1^*)^{-1/2} C_1^* (1 - C_1 C_1^*)^{-1/2} \| \leq \| (1 - C_1 C_1^*)^{-1} (C_1 - C_1 C_1^* C_1)(1 - C_1^* C_1)^{-1} \|.$$

(10.15)

But (10.15) follows from Lemma 10.10 by substituting $B = C_1$ and $A = (1 - C_1 C_1^*)^{-1/2} C_1^* (1 - C_1 C_1^*)^{-1/2}$ into inequality (10.8). □
The above results establish

**Theorem 10.12.** $B$ is a hyperbolic space.
